

(text in Italian)

1610

7 Jan With the aid of the telescope Jupiter was visible along with three fixed stars thus, of which
(diagram) none was visible without the telescope.

8 Jan It appeared thus. It was therefore direct and not retrograde as the calculators posit.
(diagram)

9 Jan Cloudy

10 Jan It appeared so, that is to say in conjunction with the westernmost star so that Jupiter hid it,
(diagram) as one may believe.

11 Jan It was in this guise and the star nearest to Jupiter was half as large as the other, and most
(diagram) close to the other, whereas on the other evenings the said three stars all appeared to be of the same size and equidistant one from another: from which it appears that there are around Jupiter three wandering stars up to this time invisible to one and all.

12 Jan It was seen in such constitution. The westerly star was somewhat smaller than the easterly,
(diagram) and Jupiter was in the middle at a distance from each equal to its diameter approximately; perhaps there was a third, quite small and quite close to Jupiter towards the east; in fact there was, I having observed with greater diligence, and the night having become darker.

13 Jan The instrument having been quite firmly fastened, four stars were seen close to Jupiter in this
(diagram) constitution, or better thus, and they all appeared to be of the same size; the space of
(diagram) the three to the west was not greater than the diameter of Jupiter, and they were noticeably closer to one another than on the other evenings; they were in a straight line precisely as before, but the middle star of those to the west was a bit elevated, or rather the westernmost somewhat depressed; all of these stars are most bright although very small, and other fixed stars which appear to be of the same size are not so brilliant.

14 Jan Cloudy

15 Jan It was thus. The closest to Jupiter was the smallest and the others were progressively larger;
(diagram) the interstices between Jupiter and the following three were equal to the diameter of Jupiter, but the fourth was about twice as far from the third; they did not make an entirely straight line, but, as the diagram shows, they were as usual most bright although small, but they did not sparkle as they had previously.

(1610)

[from here on, texts in Latin; digressions into Italian so noted]

(short note in Italian) These are to be engraved in wood in one piece, with the stars white and the rest black, and then they are to be sawed into pieces.

The preceding constitution was at Hr 3 of the night, but at Hr 7 there were only three stars with
(diagram) Jupiter in such appearance: the smallest was closest to Jupiter, the remaining two twice greater than the small one and equal to each other. The distance from Jupiter to the nearest was increased; the closest was the second, namely by half of the diameter of Jupiter. The third was a bit more distant from the second than the second from Jupiter. Indeed, another hour later the two middle stars were closer still to the extent that the space between them occupied by the smallest star was less, namely about 40 second minutes

16 Jan 1st hour of the night. Such was the constitution. 3 stars only were visible, two close to Jupiter,
(diagram) that is each distant from it by a fourth part of its (Jupiter's) diameter, always 1'; however a third star to the west was distant from it (Jupiter) by four times its (Jupiter's) diameter; those closer to Jupiter did not seem larger than the one farther off but brighter.

17 Jan 1/2 (?) hour from sunset. The configuration was of this sort. The easterly star was distant from
(diagram) Jupiter by 3'. The westerly by 11'. The easterly seemed twice greater than the other. No more than these two stars were visible. But after four hours had gone by, namely on the 5th hour, a third star began to appear which, as I conjecture, was joined with the easterly one and such was their appearance: the middle one was now as close as possible to the more easterly, namely distant from it by 20 second minutes and deflecting a bit towards the south from a straight line drawn through the outermost stars and Jupiter.

18 Jan Hr 0.20 from sunset. Such was the appearance. The more easterly star was greater than the
(diagram) other; the interval between the one to the East and the center of Jupiter was less than that between Jupiter and the one to the west, 11'. According to my estimation the diameter of Jupiter occupies 3' or something less.

19 Jan Hr 2 Thus was the configuration; namely according to a most straight line through Jupiter
(diagram) with three the stars. Between the star to the east and the center of Jupiter the interval was 6'; between Jupiter and the next 5'; between this one and the one to the west 4'. The easterly one was a bit larger than the others. I was undecided whether a star was between the easterly one and Jupiter but close to Jupiter so as almost to touch it; but at
(diagram) the 5th hour I manifestly saw it now occupying the middle place between Jupiter and the easterly star, so that the constitution was thus. However on the last viewing this star was very small; however at the 6th hour it approximately equalled the others in size.

(1610)

20 Jan Hr 1.15 Thus was the configuration . There were three stars so small that they could scarcely
 (diagram) be seen. If indeed on these last nights they appeared four times larger, they were for
 (diagram) the most part distant from Jupiter and from each other by one minute. I was uncertain
 (diagram) whether there were 2 or 3 stars from the west. About the 6th hour it was thus. The
 easterly star was 2' from Jupiter; the middle one 40" from Jupiter, from the westerly
 one indeed 20" according to my estimation. At Hr 7 indeed it was thus. There were
 three easterly stars. The nearest to Jupiter was 20" away from it. Between this one
 and the westernmost the distance was 40"; from these deflected a bit to the south
 another star which was distant from the westernmost by no more than 10" according
 to my estimation.

21 Jan Hr 0.30 The stars on the easterly side were equally distant from one another and from Jupiter
 (diagram) according to my estimation. Also there was present a star on the west distant 5' from
 the center of Jupiter. The easterly star closest to Jupiter was the smallest of all. The
 remaining three, indeed, were somewhat larger and equal to one another.

22 Jan Hr 2 Thus was the constitution. From the easterly star to the center of Jupiter it was 6'; from
 (diagram) the center of Jupiter to the more westerly, 7'. The two intermediate stars were 40"
 distant from each other; between Jupiter and the one nearest to it 1'. The middle stars
 were smaller than the outermost. They were all on the same straight line according to
 the longitude of the Zodiac, excepting the intermediate one which was farther from
 Jupiter; it declined slightly to the south.

Hr 6 They appeared thus. The easterly one, very small, was distant from Jupiter as before. The three
 (diagram) to the west were equally distant from Jupiter and from each other and the individual
 interstices were approximately $1\frac{1}{3}$. And the star nearest to Jupiter was smaller than
 the other two following. They were all on a perfectly straight line.

23 Jan Hr 0.40 from sunset Thus was the constitution. There were three stars on a straight line
 (diagram) according to the longitude of the Zodiac. The most easterly was 7' distant from the
 following; the next 6' from the westerly one. Jupiter occupied the middle place among
 them and was a bit closer to the middle one. They were about equal in size.

(1610)

Hr truly 5 Two small stars which were near to Jupiter are no longer discerned of which the
(diagram) constitution was such

(large grid)

(in Italian) one of the three of Orion's Belt

(diagram) Canis

Around Canis besides others
there are 7 stars in exactly similar configuration of which
the distant of the largest from Canis does not surpass 20 minutes.

(diagram) Canis Minor, I believe

Star A is not seen without the lens. However, seen with the lens it appears to
be of so great a size that the others are seen to be of 2nd, 3rd and 4th
magnitude less than it.

(1610)

24 Jan Hr 0.50 Such was the configuration. Three stars were visible on the same straight line with
(diagram) Jupiter except that the middle one deflected a bit to the south; they were all to the east of Jupiter, The nearest was 2' from Jupiter; the next 30'' from this; the most easterly was 9' from this. The sky was most clear.

Hr 6.15 It was so. Now only two stars appeared on an exactly straight line with Jupiter, each to the
(diagram) east; the one nearer to Jupiter was 3' from it; the other in truth was about 8' from it.

25 Jan Hr 1.40 It was thus. There were now only 2 easterly stars of which the more easterly was 5
(diagram) 5' distant from the other, the latter indeed according to estimation 6' from Jupiter. Both appeared equal and rather large.

26 Jan Hr 0.40 The position of the stars was of this sort. Now three stars were observed of which 2
(diagram) easterly ones and a third west from Jupiter; the westerly one was 5' from Jupiter; the middle one was, it seemed, 5' 20'' from the same. The more easterly one indeed was 6' from this one; they were all on the same straight line with Jupiter, of almost equal magnitude and rather large.

Hr 5.20 In truth, the constitution was as above, except that there was emerging near Jupiter from the
(diagram) east a fourth small star, smaller than the others, 40'' removed from Jupiter and slightly deflecting from the straight (line) of the other stars towards the north, as the present figure points out.

27 Jan Hr 1 from sunset. Only one small star was visible and it was easterly as in this constitution; it
(diagram) was quite small, and was 7' from Jupiter according to estimation.

28 and 29 Jan. The sky was cloudy.

30 Jan Hr 1 Thus were the stars constituted. There was one easterly star distant 2' 30'' from Jupiter,
(diagram) two in truth westerly of which the one nearer to Jupiter was 3' from it; the other was 1' from this and was smaller than the others, and declined slightly southward from the straight line on which the others along with Jupiter are found.

31 Jan Hr 2 There were two easterly ones. The one close to Jupiter was 2'20'' distant from it; the
(diagram) more easterly 30'' from this one. The westerly one was 12' (?) away from Jupiter. They were on a straight line, except that the one closer to Jupiter was elevated slightly to the north. Hr 4 Truly the two easterly ones were closer to each other, to the extent that they were only 20'' distant. In said observations the westerly star was exceedingly small.

(1610)

the Suckulae (Hyades) becoming visible (diagram)

(diagram) on a straight (line) through Jupiter and its stars at right angles to the south a certain star is distant by about 30'

(large boxed diagram) requisite description

1 Feb Hr 2 Such was the constitution. The more easterly star was 6' from Jupiter, the westerly one, (diagram) indeed, 8' to Jupiter. From the east a very small star was near, about 20" from it.

2 Feb Hr 0.40 An easterly one was 6' distant from Jupiter; from the westerly one closer to it 4'; this (diagram) from the more westerly 8'. They were all approximately of the same size. However, at the seventh hour it was thus. Now there were four stars present, 2 easterly,

(diagram) 2 westerly. The more easterly one was 4' from the next; this 1' 40" from Jupiter; Jupiter 6' from the next one, and this one from the more westerly 8'. They were all on a most straight line.

3 Feb Hr 7 Thus it was. The easterly one was 1'30" distant from Jupiter. The nearer westerly one (diagram) was 2' away; from it the other westerly one was 10' distant. They were all exactly on the same straight line, and of about the same size.

4 Feb Hr 2 There were 2 easterly stars and 2 westerly as in the opposite figure. The more easterly (diagram) one was 3' from the next, this was 0'40" away from Jupiter; Jupiter from the nearer westerly one 4'; this indeed from the next westerly one 6'. They were all in the same straight line, and of approximately the same size; the one certainly closest to Jupiter appeared to be slightly smaller.

Hour 7 They were thus. From the more easterly one to the next 0'30"; from this one to Jupiter 2'; (diagram) from Jupiter to the nearer westerly one 4'; from this to the more westerly one 3'; all equal and on a straight line, always according to the ecliptic.

(1610)

5 Feb The sky was cloudy.

6 Feb Such was the constitution. Hr 2 Only two stars were present, one to the east, 2' distant from (diagram) Jupiter; another to the west, 3' removed from Jupiter. They were on the same straight line with Jupiter.

7 Feb Two stars were present, both easterly, thus constituted. The interstices between the same and (diagram) Jupiter were 1' for both, and they were on the same straight line.

(large boxed diagram)

8 Feb Hr 1 There were three stars, all easterly as in the opposite diagram, the one next to Jupiter (diagram) was small, distant 1'20" from it; the middle one was 4' from this one and was rather large; the most easterly one, very small, was 20" from this one. They were viewed at Hr 0.40 from sunset. I was undecided as to whether there were only one or 2 stars near to Jupiter; now, in the meantime, towards sunrise, there seemed to be another one near to this, extremely small, distant 20" from the former. They were all on the same straight line constituted according to the extension of the ecliptic. Truly at Hr 3 the star near to Jupiter almost touched it; it was now only 10" distant. The others, indeed, were only slightly farther from Jupiter; the middle one was now 6' distant from Jupiter; finally at Hr 4 it was entirely in juncture with Jupiter to the extent that it was no longer discerned.

9 Feb Hr 0.30' There were present 2 easterly stars and one westerly thus: the small easterly one was (diagram) 4' distant from the next; the middle one was larger and 7' removed from Jupiter. Jupiter was 4' from the westerly one which was small.

10 Feb Hr 1.40 Two quite small stars were visible, both to the east. The more removed was 10' from (diagram) Jupiter, the closer, in truth, 0'20" and they were on the same straight line. However, at Hr 4, the closer one was no longer apparent. Indeed, as I conjecture, it was hidden behind Jupiter. The other was yet diminished so that it could hardly be discerned, although the air was quite clear, and it was greatly removed from Jupiter. Now it seemed to be 12' distant.

(1610)

11 Feb Hr 1 (diagram) There were two stars present from the east and from the west. The westerly one was distant 4' from Jupiter. The nearer easterly one was equally 4'; the more easterly was 8' distant from this. They were all quite clear and on a straight line to a hair.

But at Hr 3 (diagram) a fourth star was seen near to Jupiter as the other diagram makes clear; it was smaller than the others and 0.30'' from Jupiter and from a straight line of the aforementioned it deflected slightly to the north. They were all most bright and astonishingly conspicuous.

At Hr 5.30 (diagram) truly the easterly star near to Jupiter already occupied to a hair the middle place between Jupiter and the following star and they were all of the same magnitude and on the same straight line exactly in this way:

12 Feb Hr 0.40 (diagram) from sunset. Four stars were present, 2 from the east and 2 from the west. The more remote easterly one was 10' from Jupiter; the more remote westerly one truly 8' and these were conspicuous enough. The remaining two were very close to Jupiter and were very small especially the easterly one which was from Jupiter distant 0'40'' the westerly one truly was 1' away.

Hr 4. The small star near to Jupiter from the east no longer appeared.

13 Feb Hr 0.30 (diagram) Four stars were present, one from the east, conspicuous enough, distant from Jupiter 2' the other truly more easterly less apparent one distant from the previous one 4'; from the west 2, of which the more westerly was distant from Jupiter 4' and was conspicuous enough; a little small star came between this one and Jupiter and near to the more westerly star; it was indeed no more than 0.30 from the former; they were all on the same straight line to a tee according to the longitude of the ecliptic.

15 Feb Hr 1 (diagram) (since on the 14th the sky was obstructed by clouds) such was the position. There were 3 easterly stars, none westerly. The one close to Jupiter was 0.50'' away, the following was 0'20'' away from this; from this one truly the easternmost was 2' distant and was larger than the remaining ones; indeed those closer to Jupiter were rather small. But at approximately Hr 5, of the stars near to Jupiter only one was discerned and the distance of this one was 0.30'; the distance truly of the easternmost was indeed 4'. Hr 6 however, besides the two constituted from the east, as was just mentioned, a little star, astonishingly small, was discerned distant from Jupiter 2'.

16 Feb Hr 6 (diagram) They stood in such constitution: an easterly one was 7' from Jupiter; Jupiter from the following westerly one 5'; this one from the more westerly one 3'; they were all of almost the same magnitude and conspicuous enough, and on the same straight line exactly according to the line of the zodiac.

(1610)

- 9 Mar Hr 5 Such was the constitution: an easterly one was 7' from Jupiter; the nearest of the westerly (diagram) ones was 0.40' from it the following was 0.20'; the westerlymost one was 8' distant from Jupiter. They were all in the same straight line, only the westerly one closest to Jupiter was slightly and almost imperceptibly raised to the north or the following one declined towards the south. As for their magnitude, they were as has been noted.
- 10 Mar Hr 5 Only three stars were discerned. One was to the east 4' distant from Jupiter; two were (diagram) to the west, of which the closer to Jupiter was 1' away, the other truly more westerly was 4'. They were all in the same straight line according to the line of the ecliptic.
- 12 Mar Hr 0.30 Only two stars were visible: one rather small one to the east distant 1' from Jupiter; one, (diagram) conspicuous, to the west 4' distant.
- 18 Mar Hr 1 Two stars were present both to the east. The closer to Jupiter was 2' distant from it. The (diagram) other, more easterly, was 8' away from the same Jupiter. They were equal and not very conspicuous.
- 20 Mar Hr 2 Two stars were visible both to the west and rather conspicuous. The air was now most (diagram) clear; the one following from Jupiter was 3' distant from it. From this one indeed the more westerly one was likewise 3' away. The one closer to Jupiter was smaller than the other. I believe that the planets were in middle longitudes because no perceptible change occurred.
- 25 Mar Hr 0.30 4 planets have been seen; two to the east, of which the nearer to Jupiter was 0.30", the (diagram) more easterly likewise 0.30" from this (last mentioned planet). The westerly one closer to Jupiter was 1.40 from it; the more westerly one was 10' distant from Jupiter and was larger than the others. Now the ones nearer to Jupiter were quite small. The more westerly one then was somewhat larger than the other two and was born slightly off towards the north above a straight line drawn from the others.
- 27 Mar Hr 2.30 Three planets were present, all to the west in this position: the closest to Jupiter was 2 (diagram) away from it, the following one likewise 2' away from this (aforementioned planet). The westerlymost one indeed almost touched this (following mentioned planet). The middle one was born slightly towards the north and was exceedingly small. The closest to Jupiter was somewhat larger, but the westerlymost was as yet more apparent.
- 28 Mar Hr 1 Only one westerly star was present, 3' distant from Jupiter, and was rather conspicuous. (diagram)
- 29 Mar Two stars were visible both to the east. The closer to Jupiter was quite small and was 1' distant (diagram) from it. The more easterly one was rather conspicuous and was 3' away from Jupiter. They were in the same straight line according to the line of the Zodiac as they have always appeared.

(1610)

(note in Italian) But these people make the world in their fashion and I in its own. I have not put in the hills and the valleys, and other stars in the heavens if first I have not seen them, but you indeed have made Jupiter incorruptible without seeing it such.

- 2 Apr (diagram) Such was the constitution; three easterly ones and one westerly. The westerly one was 3' away from Jupiter. The easterly one closest to Jupiter was 1' away from it; the following one was 2' away from this; the more easterly one was 8' away from this. They were all in a straight line to a hair and were all conspicuous. In Firenzuola
- 3 Apr Hr 0.40 (diagram) Three planets were visible, one to the east, two indeed to the west. The easterly one was 9' distant from Jupiter. The closer westerly one was 1' from Jupiter; the remaining more westerly one was 3' from the other. It was brighter than the others. Florence
- 5 Apr Hr 1 (diagram) Only one easterly planet was present 2'30" distant from Jupiter and was rather conspicuous. In San Romano
- 6 Apr Hr 2 (diagram) Only one easterly one was present 5' distant from Jupiter and it was rather conspicuous. It was not, as I conjecture, the same as the preceding, but another conjoined with Jupiter on a previous night; Venus then indeed appeared. Now it was under Jupiter.
- 9 Apr Hr 1 (diagram) Four planets have been seen in this configuration: namely 2 easterly ones of which the closer to Jupiter was 2' away from it, the other likewise 2' away from this (aforementioned planet). At the same time there were two westerly ones of which the closer was 1'30" distant from Jupiter; the other was 8' distant from Jupiter. They were in the same straight line to a hair, and rather conspicuous.
- 10 Apr Hr 0.30 (diagram) Thus was the constitution: namely three easterly planets of which the closest to Jupiter was 1' 30" distant from it; the following was 5' away from Jupiter; the remaining one was indeed 5' from this.
- 11 Apr Hr 1 (diagram) 3 stars were present all to the west. The closest to Jupiter was 2' distant; the following one was 3' away from this and the most westerly indeed was 4' distant from this.
- 13 Apr Hr 0.30 (diagram) Only a pair of stars was sighted, one to the east distant 4' from Jupiter, one to the west indeed 6'.
- 14 Apr Hr 1.30 (diagram) Four planets were sighted; 2 to the east, likewise 2 to the west. The easterly one closer to Jupiter was 1' away, the other easterly one was 6' distant from Jupiter. The closer westerly one was 0'40" away, the other one 4'.
- 15 Apr (diagram) Only 2 appeared, one easterly, the other westerly.
- 16 Apr (diagram) Three were seen, all easterly. The closest to Jupiter was 2' away; the following one 2'; the easternmost 4' from this.
- 17 Apr (diagram) 3 stars were present, one to the east 9' distant from Jupiter; 2 to the west of which the closer to Jupiter was 2' distant, the more westerly was 4' distant from this.
- 18 Apr Hr 0.20 (diagram) Four planets were seen. The easterly one more removed from Jupiter was 12' from it, the closer 1'. The closer westerly one was 3' away; the more westerly one was indeed likewise 3' from this. And they were in the same straight line to a hair. At the Villa del Cappone

Hr 3 (diagram)

27 Mar Hr 0.30 (diagram) Viterbo

The more easterly was approaching the following one; now at Hr 2 it was only 1 minute away; however at Hr 3 they were almost touching each other; the distance of the closer one did not appear changed, from which it may be conjectured that it was in its middle longitude and that it is the one which describes the smallest circle, truly the more easterly one which traces the second circle from Jupiter; Hr 4 they were all entirely joined, and the distance of these from Jupiter seemed slightly changed.

28 Mar Hr 0.30 (diagram) Monterosi

Hr 3 (diagram)

Hr 4.30 (diagram) Those close to Jupiter were separated; the third from Jupiter was slightly larger than the others.

Hr 6	(diagram)
28 Jan Hr 2	(diagram)
Hr 5	(diagram)
29 Jan Hr 3	(diagram)
30 Jan Hr 2	(diagram)
31 Jan Hr 3	(diagram)
Hr 5	(diagram)

In this second observation I first used the instrument for taking intervals exactly, and I took the distance of the more easterly one accurately; the instrument was not as yet most exactly prepared.

1 Feb Hr 2	(diagram)
Hr 5	(diagram)

The distances of this second observation were observed through the instrument, but as to the hour it is not sure. Note that if in the instrument with which the distances are obtained there be noted a line which divides it according to the angle by which a line of the ecliptic divides a parallel of the equator in the place/locus of Jupiter, through the movement of Jupiter on this line it may be known if the Medicean planets travel on parallel planes of the ecliptic.

10 Feb Hr 1.50 (diagram)

Hr 4 (diagram)

Don Benedetto

Hr 6 (diagram)

12 Feb Hr 11 (diagram) The ones closest to Jupiter seemed stationary; the more westerly one truly was distant from the one closest to itself by hardly 1 semidiameter.
Don Benedetto

1612 Feb

15 Feb Hr 2 (diagram)

17 Feb Hr 0.30 (diagram)

exact Hr 1.30 (diagram)

19 Feb Hr 0.30 (diagram)

21 Feb Hr 6 (diagram) The distances were taken without the instrument.

22 Feb Hr 5 (diagram)

23 Feb Hr 0.30 (diagram)

Hr 5 (diagram) The two closest to Jupiter were almost touching each other; these observations were most exact.

After Hr 0.5 the ones closest to Jupiter had come wholly together to the extent that within 5 minutes of time, or less, a most exact conjunction is manifestly distinguished from a most perceptible separation; it was a central conjunction without any turning away of one from the other.

After Hr 0.20 they were again separate, and, as I judge, their conjunction will have lasted nearly 0.15 hour; and after the separation, the one nearer to Jupiter seemed to be raised a bit to the north, because truly its turning away was quite slight; perhaps it was present before the coming together; however, it was not noticed by me. From these observations and from the preceding one it is gathered that (#2) was in middle perigee from day 22 of this month of Feb at Hr 10.10 from noon.

25 Feb Hr 1 (diagram) to the north from Don Benedetto

26 Feb Hr 0.50 (diagram)

Hr 4.20 (diagram) perhaps 2 had come together from Don Benedetto

28 Feb Hr 0.20 (diagram)

Hr 1.20 (diagram)

Hr 3 (diagram)

1612 Feb

Hr 4.	(diagram)
29 Feb Hr 0.20.	(diagram) both were raised to the north
Hr 1.	(diagram)
Hr 2.	(diagram)
Hr 4.30'	(diagram)
Hr 6.	(diagram) the westerly one was declining to the south and was moving perceptibly to the east, the other stars remaining at nearly the same distances.
1 Mar Hr .40'	(diagram)
Hr 2.	(diagram)
Hr 4.10'	(diagram)
Hr 5.20'	(diagram)
Hr 6.30	(diagram) The two easterly ones closer to Jupiter at this moment were conjoined, and the one which was closest to Jupiter was tending slightly to the east because it was declining to the south.

And Hr 7. They were again separate, the same slight turning away remaining; and there was from the beginning of the true coming together until the beginning of the complete separation an interval of about Hr 0.30'

1612 March

2 Mar Hr 3.30 (diagram) to the south

Hr 5.30 The two middle easterly ones were conjoined, and because the one turned southward was declining, it seemed to be touching the other laterally; then also the westerly one was hidden behind Jupiter.

4 Mar Hr 0.30 (diagram) to the north

Hr 6 (diagram)

Hr 6.50 (diagram) The westerly ones were conjoined with a turning away to the north of the one which was advancing to the west.

10 Mar Hr 3 (diagram) They were almost touching each other and (#2) more westerly raised to the north.

And Hr 4.30 The westerly were still entirely touching each other.

(diagram)

12 Mar Hr 0.50 (diagram)

Hr 4 (diagram)

13 Mar Hr 4 (diagram)

Hr 4.20 The easterly ones were touching each other.

Hr 5.40 (diagram)

And the easterly ones were separated again, and were hardly deflected from a straight line; the one nearer to Jupiter now inclined to the north, the more remote truly indeed slightly to the south.

14 Mar Hr 0.30 (diagram) to the north

Hr 1.25 (diagram)

Hr 3 (diagram)

The two closer to Jupiter were touching each other, and after Hr 0.30 were perfectly conjoined; and were again after Hr 0.30 separated, so that from this contact till the utmost separation there elapsed the space of one hour.

15 Mar Hr 0.30 (diagram)

Observations

Mss. Gal., P.III, T.IV, car.72r.

1612

7 Nov Hr 1 before sunrise; this is (?)

6 Nov Hr ... after noon

(diagram)

20 Nov Hr 2 before sunrise or

19 Nov Hr ... after noon

(diagram) I was doubtful about the first [prima, feminine: stella] easterly one.

(diagram) After an hour such was the constitution.

At the same time I saw Mercury, and its disc appeared most like Jupiter's or slightly larger; its diameter, then, scarcely equalled a fifth part of the diameter of Venus.

22 Nov Hr 0.30 before sunrise; that is on 21 Nov Hr ... from noon

(diagram)

25 Nov Hr 2 before sunrise; on 24 Nov Hr 17.25 from noon.

(diagram)

(diagram) after an hour thus; in which hour Mercury was elevated 0.30 degree; it was Hr 1.15 before sunrise and Hr 18.10 after noon. And after Hr

(diagram) 0.30 thus 24 Nov

27 Nov Hr 2 before sunrise; on 26 Nov Hr ... from noon

(diagram) a certain small star A in a similar site appeared.

(diagram) before sunrise Hr 0.30 and Jupiter perceptibly approached fixed A.

28 Nov Hr 4 before sunrise; on 27 Nov Hr 15.28. from noon

Venus was then rising.

(diagram)

(diagram) after Hr 1.30

(diagram) Hr 0.30 before sunrise

29 Nov Hr 2.30 before sunrise; on 28 Nov Hr [blank] from noon

(diagram)

(diagram) after an hour

1612

3 Dec Hr 1 before sunrise; on 2 Dec Hr 2 from noon

(diagram) doubtful

5 Dec Hr 1.15' before sunrise on 4 Dec Hr 18.17 from noon

(diagram) was receding from Jupiter

was nearing

(diagram) Hour 0.30 before sunrise

6 Dec Hr 4.0' before sunrise on 5 Dec Hr 15.54 from noon

Venus was rising.

(diagram)

after Hr 0.30 (diagram)

after Hr 1.45 (diagram) first observation

and after Hr 3.20 (diagram) from first observation

finally Hr 0.30 before sunrise thus was an exact observation

(diagram) it was indeed raised a bit towards north

7 Dec Hr 1.40 before sunrise on 6 Dec Hr 17.54 from noon

(diagram) slightly deflecting to the South

After Hr 1 (diagram) thus, and the 2 closest to Jupiter were almost touching; however, on contact they did not turn aside, although through Hr 0.20 they were observed in the same condition; and the distance from Jupiter of the smaller one seemed slightly diminished, from which it is concluded that it was in its mid remotion.

The diameter of Mars was determined through collation to the moon since it was in opposition with the sun. Degree 0 0'12"

8 Dec Hr 2.30 after the rising of Jupiter, which was Hr 4.30 before sunrise on 7 Dec Hr 15.5 from noon

(diagram)

The 2 closer to Jupiter were barely touching each other and at approximately Hr 1.30 are hardly perceptibly separated; however, after Hr 2.10 after the first observation they were 0.40' distant from each other; however, the hour 2.50 from the first observation thus:

(diagram) slightly to the south

after Hr 3.20 thus:

(diagram)

after Hr 4.30 (diagram)

finally before sunrise Hr 0.30

(diagram)

9 Dec Hr 1.40 before sunrise, which is 8 Dec Hr 17.56 from noon

(diagram)

after Hr 1.0 (diagram)

.

11 Dec Hr 1.25 before sunrise; on 10 Dec Hr. 1.25 [lined out?] from noon

(diagram)

13 Dec Hr 4.30 before sunrise; on 12 Dec Hr 15 from noon

(diagram)

after Hr 1 (diagram) after the rising of Venus Hr 0.30 at Hr 16 from noon

after Hr 2 (diagram) from first observation at Hr 17 from noon

(diagram) and after first observation Hr 2.40

Hr 0.30 before sunrise the 2 closer to Jupiter were almost touching each other and perhaps were truly touching each other and therefore by means of this most exact observation a correction of the tables can be arrived at.

14 Dec Hr 2.15 before sunrise; on 13 Dec Hr [entry inked out] from noon

(diagram)

(diagram) after an hour

(diagram) before sunrise Hr 0.40

15 Dec Hr 4.30 before sunrise; on 14 Dec Hr 15.6 from noon

(diagram) after Hr 3

slightly to the south

(diagram)

1612

16 Dec Hr 1 .30 before sunrise; on 15 Dec Hr 18.8 from noon

(diagram) to the north slightly

after Hr 1 thus (diagram)

17 Dec Hr 0.20 after the rising of Venus, which was Hr 3. before sunrise; on 16 Dec Hr 15.47 from noon.

(diagram)

The westerly ones were 2, conjoined, namely (#2) and (#3) and stayed ever in conjunction, so that scarcely at Hr 0.20 before sunrise something of the beginning of a separation was able to be discerned, truly thus, and the more westerly seemed to be raised slightly to the north; and was then distant from Jupiter 8 semidiameters, which observation marvelously leads to an emendation of the tables.

18 Dec Hr 0.20 after the rising of the moon, which was Hr 4.0 before sunrise; on 17 Dec Hr 15.37 from noon.

(diagram)

After 2 Hrs when the ones closer to Jupiter were indeed more fully separated, one of them, falling into the shadow of Jupiter, no longer appeared; the other truly was distant from Jupiter 3.20.

19 Dec Hr 0.30 before sunrise; on 18 Dec Hr [blank]

(diagram)

20 Dec Hr 1 after rising of Jupiter; on 19 Dec Hr [blank]

(diagram)

The others were hidden behind Jupiter and the westerly one hastened to conjunction. We wanted to stay up all night so that we might see the separation of the others, which after 4 hours we did not see; thence, seized and overcome by sleep, it did not befall us any longer to observe.

1612

27 Dec Hr 15.46 from noon, while Venus was rising

(diagram)

Before sunrise 0.30 two westerly ones were closely conjoined; they were distant now 0.20 according to longitude, but the more westerly had such great longitude that it appeared that in this connection it almost and just almost touched the other; and at the same hour a fourth star was present from the west and the easterly one was made more remote; and such was the configuration; and the tables corresponded to a hair.

(diagram)

29 Dec Hr 19.0 from noon doubtful because of clouds

1613

2 Jan Hr 12 from noon

(diagram)

(diagram)

Hr 16.30 or Hr 2.30 before sunrise of the following day

3 Jan Hr 11 from noon after the rising of Jupiter Hr 0.30 it was deflecting fairly to the south.

(diagram)

before sunrise Hr 0 (diagram) by estimation

5 Jan Hr (6.34 lined out) 7.12 from sunset, from noon truly Hr 11. 38

(diagram) most exact observation

after Hr 6.18 (diagram)

1613

20 Jan Hr 10.30 from noon

(diagram)
